## Chem 4A, Fall 2010

Midterm Exam 1, September 22, 2010.
Prof. Head-Gordon, Prof. Saykally

Name: KEY
GSI:

Grade: $\quad$ 1. (5 points)
2. (5 points)
3. (4 points) $\qquad$
4. (7 points) $\qquad$

Total:

Closed book exam. There are 6 pages. Calculators are OK. Show all working. Use back side of pages for scribble paper. Don't spend too much time on any one problem! Read all parts of each question and include units in all answers.

Some possibly useful facts and figures:

$$
\begin{aligned}
& R=8.3145 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1} \\
& h=6.6261 \times 10^{-34} \mathrm{~J} \mathrm{~s}^{-1} \\
& c=2.9979 \times 10^{8} \mathrm{~m} \mathrm{~s}^{-1} \\
& m_{e}=9.1094 \times 10^{-31} \mathrm{~kg}^{2} \\
& N_{0}=6.0221 \times 10^{23} \mathrm{~mol}^{-1}
\end{aligned}
$$

molar volume at $\mathrm{STP}=22.4 \mathrm{~L}$

$$
1 \mathrm{~J}=1 \mathrm{~kg} \mathrm{~m}^{2} \mathrm{~s}^{-2}
$$

Some possibly relevant equations:

Planck relation:
$E=h v$
de Broglie relation:
wave equation:
uncertainty principle
particle-in-a-box
hydrogen atom
linear momentum
kinetic energy
$p=h / \lambda$
$c=v \lambda$
$E_{n}=\frac{n^{2} h^{2}}{8 m L^{2}}$
$p=m v$
$\Delta p \Delta x \geq h / 4 \pi$
$\Psi_{n}=\sqrt{\frac{2}{L}} \sin \frac{n \pi x}{L}$
$E_{n}=-\frac{Z^{2}}{n^{2}} R_{\infty}$ $\mathrm{R}_{\infty}=2.18 \times 10^{-18} \mathrm{~J}$
$T=\frac{1}{2} m v^{2}=p^{2} / 2 m$

1. Stoichiometry and elementary bonding theory. A compound is being tested as a possible rocket propellant, and elemental analysis reveals that it is $18.54 \% \mathrm{~F}, 34.61 \% \mathrm{Cl}$, and $46.85 \% \mathrm{O}$ by mass (relative atomic masses are $18.998(\mathrm{~F}), 35.343(\mathrm{Cl}), 15.994(\mathrm{O})$ ).
(a) (3 points) Determine the empirical formula of the compound.

| F: | 18.54 g | $\div$ | $\div 8.998 \mathrm{~g} \mathrm{~mol}^{-1}$ | $=0.9759 \mathrm{~mol}$ |
| :--- | :--- | :--- | :--- | :--- |
| CI: | 34.61 g | $\div$ | $35.343 \mathrm{~g} \mathrm{~mol}^{-1}$ | $=0.9793 \mathrm{~mol}$ |
| O: | 46.85 g | $\div$ | $15.994 \mathrm{~g} \mathrm{~mol}^{-1}$ | $=2.929 \mathrm{~mol}$ |

$\mathrm{F}: \mathrm{Cl}: \mathrm{O}=1: 1: 3$
$\mathrm{CIFO}_{3}$
(b) (1 point) If the molecular formula is the same as the empirical formula, write a Lewis diagram for the molecule, assuming that Cl is at the center.

(c) (1 point) Use the VSEPR model to predict the geometry of the molecule.

Tetrahedral
2. Waves behaving like particles and particles behaving like waves...
(a) (2 points) The work function of the metal chromium is $7.2 \times 10^{-19} \mathrm{~J}$. If chromium is exposed to radiation with wave length $2.0 \times 10^{-7} \mathrm{~m}$, can photoelectrons be ejected, and if so, with what kinetic energy release?

$$
\begin{aligned}
& E_{\max }=\mathrm{h}-\Phi \\
& \Phi=7.2 * 10^{-19} \mathrm{~J} \\
& \mathrm{E}_{\text {radiation }}=\mathrm{h} * \mathrm{c} \div \lambda=\mathrm{h} * \mathrm{c} \div\left(2.0 * 10^{-7} \mathrm{~m}\right)=9.94 * 10^{-19} \mathrm{~J}
\end{aligned}
$$

So yes, photons can be ejected, and their energies will be:

$$
E_{\max }=h v-\Phi=9.94 * 10^{-19} \mathrm{~J}-7.2 * 10^{-19} \mathrm{~J}=2.7 * 10^{-19} \mathrm{~J}
$$

(b) ( 3 points) Calculate the kinetic energy necessary to achieve a de Broglie wavelength of $2 \AA$ for helium atoms and electrons (relative atomic mass of He is 4.003). Use your results to comment on which approach would be likely to cause more surface damage in imaging a surface by diffraction.

$$
\mathrm{T}=\mathrm{p}^{2} \div\left[22^{*} \mathrm{~m}\right]=\mathrm{h}^{2} \div\left[\lambda^{2 *} 2^{*} \mathrm{~m}\right]
$$

Helium atom:

$$
\begin{aligned}
\text { mass } & =4.003 \mathrm{~g} \mathrm{~mol}^{-1} \div\left(6.0221 * 10^{23} \mathrm{~mol}^{-1}\right) \\
& =6.65 * 10^{-27} \mathrm{~kg} \\
\mathrm{~T}=\mathrm{h}^{2} & \div\left[\left(2 * 10^{-10} \mathrm{~m}\right) * 2 *\left(6.65 * 10^{-27} \mathrm{~kg}\right)\right]=8.3 * 10^{-22} \mathrm{~J}
\end{aligned}
$$

Electron:

$$
\mathrm{T}=\mathrm{h}^{2} \div\left[\left(2 * 10^{-10} \mathrm{~m}\right) * 2 *\left(9.1094 * 10^{-31} \mathrm{~kg}\right)\right]=6.0^{*} 10^{-22} \mathrm{~J}
$$

Therefore an electron is likely to cause more damage.
3. Bohr model for 1-electron atoms, and the Lyman series.
(a) (2 points). The Lyman series involves the emission of radiation from excited H atoms to their ground state. Calculate the Lyman frequency of radiation that is emitted when the initial level is $\mathrm{n}=3$.

For emission, $\mathrm{E}_{\mathrm{i}}=\mathrm{E}_{\mathrm{f}}+\mathrm{h} v$

$$
\begin{aligned}
v & =E_{1}-E_{f}=\left[R_{\infty} * Z^{2} *\left(1 / n_{f}^{2}-1 / n_{i}^{2}\right)\right] \div h \\
& =\left[R_{\infty} * Z^{2} *(1 / 1-1 / 9)\right] \div h \\
& =2.92 * 10^{15} s^{-1}
\end{aligned}
$$

(b) (2 points). If $\mathrm{He}^{+}$ions are present in the same region as the emitting H atoms, such as in close to stars, explain fully whether they can or cannot absorb the radiation emitted in (a) above.

For $\mathrm{He}^{+}$ions to absorb the radiation from part (a), they would have to have an energy transition such that $E_{f}-E_{i}=(8 / 9){ }^{*} R_{\infty}$

Therefore, (8/9) * $\mathrm{R}_{\infty}=\left[\mathrm{R}_{\infty}{ }^{*} 2^{2}{ }^{*}\left(1 / \mathrm{n}_{f}^{2}-1 / \mathrm{n}_{i}^{2}\right)\right]$
$(8 / 9)=4 / n_{f}^{2}-4 / n_{i}^{2}$
By inspection, $\mathrm{n}_{\boldsymbol{i}}=\mathbf{2}$ and $\mathrm{n}_{\mathrm{f}}=\mathbf{6}$
4. The particle in a box and the zero point energy.
(a) (2 points) Use Heisenberg's uncertainty principle to estimate the minimum uncertainty in momentum (and thus the minimum momentum) for an electron in a box of length $2 \AA$.
$\Delta p^{*} \Delta x \geq h \div\left[4^{*} \pi\right]$
$\Delta \mathrm{p} \geq \mathrm{h} \div\left[4^{*} \pi^{*} \Delta \mathrm{x}\right]$
$\Delta p \geq h \div\left[4^{*} \pi \pi^{*}\left(2{ }^{*} 10^{-10} \mathrm{~m}\right)\right]$
$\Delta \mathrm{p} \geq 2.6{ }^{*} 10^{-25} \mathrm{~kg} \mathrm{~m} \mathrm{~s}^{-1}$
(b) (1 point) From your result in (a), estimate the minimum energy associated with a particle in a box of length $2 \AA$.

## Option 1:

$$
\begin{aligned}
\mathrm{E}=\mathrm{T}+\mathrm{V}=\mathrm{T} & =\mathrm{p}^{2} \div[2 * \mathrm{~m}] \\
& =\left(2.6^{*} 10^{-25} \mathrm{~kg} \mathrm{~m} \mathrm{~s}^{-1}\right)^{2} \div\left[2 *\left(9.1094^{*} 10^{-31} \mathrm{~kg}\right)\right] \\
& =3.8 * 10^{-20} \mathrm{~J}
\end{aligned}
$$

## Option 2:

$$
\begin{aligned}
\mathrm{E} & =\mathrm{n}^{2 *} \mathrm{~h}^{2} \div\left[8 * \mathrm{~m}^{*} \mathrm{~L}^{2}\right] \\
& =1^{2 *} \mathrm{~h}^{2} \div\left[8 *\left(9.1094 * 10^{-31} \mathrm{~kg}\right) *\left(2 * 10^{-10} \mathrm{~m}\right)^{2}\right] \\
& =1.5^{*} 10^{-18} \mathrm{~J}
\end{aligned}
$$

(c) (2 points) Suppose an electron is confined to a box of length $2 \AA$. What photon energy would be required to promote the electron from the $n=2$ level to the $n=3$ level?

$$
\begin{aligned}
& E=n^{2}{ }^{*} h^{2} \div\left[8 * m^{*} L^{2}\right] \\
& E_{3}-E_{2}=(9-4)^{*} h^{2} \div\left[8 *\left(9.1094 * 10^{-31} \mathrm{~kg}\right)^{*}\left(2 * 10^{-10}\right)^{2}\right] \\
& \\
& \\
& =7.5 * 10^{-18} \mathrm{~J}
\end{aligned}
$$

(d) (2 points) Make a sketch of the wave function and probability density associated with the $n=3$ level of the particle in a box.

Probability Density
