INSTRUCTIONS

• You have 2 hours to complete the exam.

• The exam is closed book, closed notes, closed computer, closed calculator, except one hand-written 8.5" × 11" crib sheet of your own creation and the official CS 61A midterm 1 study guide.

• Mark your answers on the exam itself. We will not grade answers written on scratch paper.

All the work on this exam is my own. (please sign)
1. (12 points) Evaluators Gonna Evaluate

For each of the expressions in the table below, write the output displayed by the interactive Python interpreter when the expression is evaluated. The output may have multiple lines. If an error occurs, write “Error”.

*Hint:* No answer requires more than 5 lines. (It’s possible that all of them require even fewer.)

The first two rows have been provided as examples.

*Recall:* The interactive interpreter displays the value of a successfully evaluated expression, unless it is None.

Assume that you have started `python3` and executed the following statements:

```python
def jazz(hands):
    if hands < out:
        return hands * 5
    else:
        return jazz(hands // 2) + 1

def twist(shout, it, out=7):
    while shout:
        shout, out = it(shout), print(shout, out)
    return lambda out: print(shout, out)

hands, out = 2, 3
```

<table>
<thead>
<tr>
<th>Expression</th>
<th>Interactive Output</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pow(2, 3)</code></td>
<td>8</td>
</tr>
<tr>
<td><code>print(4, 5) + 1</code></td>
<td><code>4 5</code></td>
</tr>
<tr>
<td></td>
<td><code>Error</code></td>
</tr>
<tr>
<td><code>print(None, print(None))</code></td>
<td></td>
</tr>
<tr>
<td><code>jazz(5)</code></td>
<td></td>
</tr>
<tr>
<td><code>(lambda out: jazz(8))(9)</code></td>
<td></td>
</tr>
<tr>
<td><code>twist(2, lambda x: x-2)(4)</code></td>
<td></td>
</tr>
<tr>
<td><code>twist(5, print)(out)</code></td>
<td></td>
</tr>
<tr>
<td><code>twist(6, lambda hands: hands-out, 2)(-1)</code></td>
<td></td>
</tr>
</tbody>
</table>
2. (12 points) Environmental Policy

(a) (6 pt) Fill in the environment diagram that results from executing the code below until the entire program is finished, an error occurs, or all frames are filled. You may not need to use all of the spaces or frames.

A complete answer will:
- Add all missing names and parent annotations to all local frames.
- Add all missing values created or referenced during execution.
- Show the return value for each local frame.

```python
def the(donald):
    return donald + 5

def clin(ton):
    def the(race):
        return donald + 6
    def ton(ga):
        donald = ga - 1
        return the(4) - 3
    return ton
donald, duck = 2, clin(the)
duck = duck(8)
```

Global frame
- `the` value: ___________
- `clin` value: ___________
- `donald` value: ___________
- `duck` value: ___________

f1: _________ [parent=___________]
- Return Value

f2: _________ [parent=___________]
- Return Value

f3: _________ [parent=___________]
- Return Value
(b) (6 pt) Fill in the environment diagram that results from executing the code below until the entire program is finished, an error occurs, or all frames are filled. You may not need to use all of the spaces or frames. The `<line ...>` annotation in a lambda value gives the line in the Python source of a lambda expression.

A complete answer will:
• Add all missing names and parent annotations to all local frames.
• Add all missing values created or referenced during execution.
• Add all missing parents of function values.
• Show the return value for each local frame.

```python
def inside(out):
    anger = lambda fear: fear(disgust)
    fear = lambda disgust: anger(out)
    disgust = 3
    fear(5)
    fear, disgust = 2, 4
    inside(lambda fear: fear + disgust)
```

Global frame

```
inside
  func inside(out) [parent=Global]

local frame 1

func λ(fear) [parent=Global]
  func λ(disgust) [parent=Global]
  Return Value
f1: inside [parent=Global]
  fear
  disgusting
  Return Value
f2: __________ [parent=__________]
  __________ [parent=__________]
  Return Value
f3: __________ [parent=__________]
  __________ [parent=__________]
  Return Value
f4: __________ [parent=__________]
  __________ [parent=__________]
  Return Value
```
3. (10 points) Digit Fidget

**IMPORTANT DEFINITION** Each digit in a non-negative integer $n$ has a digit position. Digit positions begin at 0 and count from the right-most digit of $n$. For example, in 568789, the digit 9 is at position 0 and digit 7 is at position 2. The digit 8 appears at both positions 1 and 3.

(a) (3 pt) Implement the `find_digit` function, which takes a non-negative integer $n$ and a digit $d$ greater than 0 and less than 10. It returns the largest (left-most) position in $n$ at which digit $d$ appears. If $d$ does not appear in $n$, then `find_digit` returns False. You may not use recursive calls.

```python
def find_digit(n, d):
    """Return the largest digit position in n for which d is the digit."
    i, k = 0, ______________________________________________________________
    while n:
        n, last = n // 10, n % 10
        if last == _________________________________________________________ :
            i = i + 1
        return _________________________________________________________________
```

(b) (2 pt) Circle all values of $y$ for which the final expression below evaluates to True. Assume that `find_digit` is implemented correctly. The `compose1` function appears on the left column of page 2 of your study guide.

```
f = lambda x: find_digit(234567, x)
compose1(f, f)(y) == y
```
(c) (3 pt) Implement `luhn_sum`. The Luhn sum of a non-negative integer \( n \) adds the sum of each digit in an even position to the sum of doubling each digit in an odd position. If doubling an odd digit results in a two-digit number, those two digits are summed to form a single digit. You may not use recursive calls or call `find_digit` in your solution.

```python
def luhn_sum(n):
    """Return the Luhn sum of n."
    >>> luhn_sum(135)   # 1 + 6 + 5
    12
    >>> luhn_sum(185)   # 1 + (1+6) + 5
    13
    >>> luhn_sum(138743) # From lecture: 2 + 3 + (1+6) + 7 + 8 + 3
    30
    """
    def luhn_digit(digit):
        x = digit * ______________________________________________________
        return (x // 10) + _______________________________________________
    total, multiplier = 0, 1
    while n:
        n, last = n // 10, n % 10
        total = total + luhn_digit(last)
        multiplier = ______________________________________________________ - multiplier
    return total
```

(d) (2 pt) A non-negative integer has a valid Luhn sum if its Luhn sum is a multiple of 10. Implement `check_digit`, which appends one additional digit to the end of its argument so that the result has a valid Luhn sum. Assume that `luhn_sum` is implemented correctly.

```python
def check_digit(n):
    """Add a digit to the end of n so that the result has a valid Luhn sum."
    >>> check_digit(153)   # 2 + 5 + 6 + 7 = 20
    1537
    >>> check_digit(13874)
    138743
    """
    return _________________________________________________________________
```
4. (6 points) Zombies!

**IMPORTANT** In this question, assume that all of \( f \), \( g \), and \( h \) are functions that take one non-negative integer argument and return a non-negative integer. You do not need to consider negative or fractional numbers.

(a) (4 pt) Implement the higher-order function `decompose1`, which takes two functions \( f \) and \( h \) as arguments. It returns a function \( g \) that relates \( f \) to \( h \) in the following way: For any non-negative integer \( x \), \( h(x) \) equals \( f(g(x)) \). Assume that `decompose1` will be called only on arguments for which such a function \( g \) exists. Furthermore, assume that there is no recursion depth limit in Python.

```python
def decompose1(f, h):
    """ Return g such that h(x) equals f(g(x)) for any non-negative integer x. ""
    return g

>>> add_one = lambda x: x + 1
>>> square_then_add_one = lambda x: x * x + 1
>>> g = decompose1(add_one, square_then_add_one)
>>> g(5)
25
>>> g(10)
100
""

def g(x):
    def r(y):
        if ____________________________________________________________ :
            return ____________________________________________________
        else:
            return ____________________________________________________
    return r(0)
```

(b) (2 pt) Write a number in the blank so that the final expression below evaluates to 2015. Assume `decompose1` is implemented correctly. The `make_adder` and `compose1` functions appear on the left column of page 2 of your study guide.

```python
e, square = make_adder(1), lambda x: x*x
decompose1(e, compose1(square, e))(3) + ____________________________
```
